# Requirements Analysis and Specifications

Before we start to develop our software, it becomes quite essential for us to understand and document the exact requirement of the customer. Experienced members of the development team carry out this job. They are called as **system analysts.**

The analyst starts *requirements gathering and analysis* activity by collecting all information from the customer which could be used to develop the requirements of the system. He then analyzes the collected information to obtain a clear and thorough understanding of the product to be developed, with a view to remove all ambiguities and inconsistencies from the initial customer perception of the problem.

# Requirements Analysis and Specifications

The following basic questions pertaining to the project should be clearly understood by the analyst in order to obtain a good grasp of the problem:

☐ What is the problem?

☐ Why is it important to solve the problem?

☐ What are the possible solutions to the problem?

☐ What exactly are the data input to the system and what exactly are the data output by the system?

☐ What are the likely complexities that might arise while solving the problem?

☐ If there are external software or hardware with which the developed software has to interface, then what exactly would the data interchange formats with the external system be?

# Requirements Analysis and Specifications

## Parts of a SRS document

The important parts of SRS document are:

 Functional requirements of the system

 Non-functional requirements of the system, and
 Goals of implementation

# Requirements Analysis and Specifications

## Functional requirements

<mark>The functional requirements part discusses the functionalities required from the system.</mark> The system is considered to perform a set of high-level functions $\{f_i\}$. The functional view of the system is shown in figure next slide. Each function $f_i$ of the system can be considered as a transformation of a set of input data (ii) to the corresponding set of output data ($o_i$). The user can get some meaningful piece of work done using a high-level function.

# Requirements Analysis and Specifications

A system performing a set of functions

# Requirements Analysis and Specifications

## Nonfunctional requirements

Nonfunctional requirements deal with the characteristics of the system which cannot be expressed as functions - such as the maintainability of the system, portability of the system, usability of the system, etc.

## Goals of implementation

The goals of implementation part documents some general suggestions regarding development. These suggestions guide trade-off among design goals. The goals of implementation section might document issues such as revisions to the system functionalities that may be required in the future, new devices to be supported in the future, reusability issues, etc. These are the items which the developers might keep in their mind during development so that the developed system may meet some aspects that are not required immediately.

# Requirements Analysis and Specifications

## Identifying functional requirements from a problem description

The high-level functional requirements often need to be identified either from an informal problem description document or from a conceptual understanding of the problem. Each high level requirement characterizes a way of system usage by some user to perform some meaningful piece of work. There can be many types of users of a system and their requirements from the system may be very different. So, it is often useful to identify the different types of users who might use the system and then try to identify the requirements from each user's perspective.

# Requirements Analysis and Specifications

**Example: -**

Consider the case of the library system, where –

**F1:** Search Book function

**Input:** an author's name

**Output:** details of the author's books and the location of these books in the library

The function Search Book (F1) takes the author's name and transforms it into book details. Functional requirements actually describe a set of high-level requirements, where each high-level requirement takes some data from the user and provides some data to the user as an output. Also each high-level requirement might consist of several other functions.

# Requirements Analysis and Specifications

## Documenting functional requirements

For documenting the functional requirements, we need to specify the set of functionalities supported by the system. A function can be specified by identifying the state at which the data is to be input to the system, its input data domain, the output data domain, and the type of processing to be carried on the input data to obtain the output data. Let us first try to document the withdraw-cash function of an ATM (Automated Teller Machine) system. The withdraw-cash is a high-level requirement. It has several sub-requirements corresponding to the different user interactions. These different interaction sequences capture the different scenarios.

# Requirements Analysis and Specifications

**Example: -** Withdraw Cash from ATM

**R1: withdraw cash**

Description: The withdraw cash function first determines the type of account that the user has and the account number from which the user wishes to withdraw cash. It checks the balance to determine whether the requested amount is available in the account. If enough balance is available, it outputs the required cash; otherwise it generates an error message.

R1.1 select withdraw amount option

Input: "withdraw amount" option

Output: user prompted to enter the account type

# Requirements Analysis and Specifications

R1.2: select account type

Input: user option

Output: prompt to enter amount

R1.3: get required amount

Input: amount to be withdrawn in integer values greater than 100 and less than 10,000 in multiples of 100.

Output: The requested cash and printed transaction statement.

Processing: the amount is debited from the user's account if sufficient balance is available, otherwise an error message displayed

# Requirements Analysis and Specifications

## Properties of a good SRS document

The important properties of a good SRS document are the following:

**Concise:** The SRS document should be concise and at the same time unambiguous, consistent, and complete. Verbose and irrelevant descriptions reduce readability and also increase error possibilities.

**Structured:** It should be well-structured. A well-structured document is easy to understand and modify. In practice, the SRS document undergoes several revisions to cope up with the customer requirements. Often, the customer requirements evolve over a period of time. Therefore, in order to make the modifications to the SRS document easy, it is important to make the document well-structured.

# Requirements Analysis and Specifications

## Properties of a good SRS document

**Black-box view:** It should only specify what the system should do and refrain from stating how to do these. This means that the SRS document should specify the external behavior of the system and not discuss the implementation issues. The SRS document should view the system to be developed as black box, and should specify the externally visible behavior of the system. For this reason, the SRS document is also called the black-box specification of a system.

**Conceptual integrity:** It should show conceptual integrity so that the reader can easily understand it.

# Requirements Analysis and Specifications

## Properties of a good SRS document

**Response to undesired events:** It should characterize acceptable responses to undesired events. These are called system response to exceptional conditions.

**Verifiable:** All requirements of the system as documented in the SRS document should be verifiable. This means that it should be possible to determine whether or not requirements have been met in an implementation.

# Requirements Analysis and Specifications

## Problems without a SRS document

The important problems that an organization would face if it does not develop a SRS document are as follows:

- Without developing the SRS document, the system would not be implemented according to customer needs.

- Software developers would not know whether what they are developing is what exactly required by the customer.

- Without SRS document, it will be very much difficult for the maintenance engineers to understand the functionality of the system.

- It will be very much difficult for user document writers to write the users' manuals properly without understanding the SRS document.

# Requirements Analysis and Specifications

 It would be very much difficult to understand that document.

 It would be very much difficult to modify that document.

 Conceptual integrity in that document would not be shown.

 The SRS document might be unambiguous and inconsistent.
